

Cashew Caching System

Cashew uses a cache-first execution model for formulas and provider calls. The backend owns cache state, and the frontend never calls providers directly.

Core rule

If two formulas have the same formula identity and the same resolved inputs, they should reuse the same stored result.

What the cache stores

- cache entries live inside the document JSON
- formula outputs are keyed deterministically
- provider results are preserved so reopening a file does not force a new call

Practical effect

- editing a referenced cell invalidates dependent results
- identical reruns reuse existing outputs when inputs do not change
- the spreadsheet stays predictable and cheap to iterate on
